Keywords: Quantitative easing Large-scale asset purchases Preferred habitat Optimal monetary policy

## 1. Introduction

## ABSTRACT

In response to the Great Financial Crisis, the Federal Reserve, the Bank of England and many other central banks have adopted unconventional monetary policy instruments. We investigate if one of these, purchases of long-term government debt, could be a valuable addition to conventional short-term interest rate policy even if the main policy rate is not constrained by the zero lower bound. To do so, we add a stylised financial sector and central bank asset purchases to an otherwise standard New Keynesian DSGE model. Asset quantities matter for interest rates through a preferred habitat channel. If conventional and unconventional monetary policy instruments are coordinated appropriately then the central bank is better able to stabilise both output and inflation.

The Great Financial Crisis has seen the emergence of monetary policy instruments that are often described as "unconventional". The events of 2007–2008 forced monetary policy authorities to adopt new tools, even though they had little previous experience with them and there was considerable uncertainty about their likely impact. The general belief was that unconventional policy was an emergency response that would be phased out once the crisis was over. However, if it is designed carefully it may help a central bank reach its objectives even in non-crisis times.

This paper investigates whether the unconventional policy of central banks purchasing long-term government debt could be useful even after the Great Financial Crisis has passed. We obtain our results in a New Keynesian DSGE model with a stylised financial sector and a Taylor-type policy rule for central bank asset purchases. Asset quantities matter because of the behaviour of banks and the incompleteness of financial markets. Households can only transfer income between periods with the help of banks, who invest the deposits they receive into government bonds. Banks allocate deposits into government bonds of different maturities according to a perception that savers are heterogeneous with respect to their preferred investment horizons. Central bank purchases of long-term government bonds reduce the supply of long-term debt available to the private sector, which increases the marginal willingness of banks to pay for it. This reduces yields on long-term debt, discourages saving, and hence

increases output and inflation. When the policy parameters are chosen optimally, a combination of conventional and unconventional policies leads to significantly lower losses compared to when the central bank uses only conventional policies.

Central bank purchases of government bonds in our model have an effect through a "preferred habitat" channel of the type identified by Modigliano and Sutch (1966), and later developed by Vayanos and Vila (2009). The idea is that investors see government bonds of different maturities as imperfect substitutes and so are willing to pay a premium on bonds of their preferred maturity. The quantities of assets available then matter for prices and returns; if the central bank purchases government debt of a particular maturity then the supply of that asset to the private sector is reduced, its price rises and its return falls. The preferred habitat channel operates in our model as banks hold government debt of different maturities in response to a perception that savers have heterogeneous investment horizons. The closest models to ours are Andrés et al. (2004) and Chen et al. (2012), although they consider different mechanisms and have less emphasis on implications for optimal policy coordination.

The main focus of the current unconventional monetary policy literature is on credit easing, i.e. central bank purchases of private financial assets.<sup>1</sup> An important exception is Eggertsson and Woodford (2003), who examine central bank purchases of government debt. They argue that unconventional monetary policy works by acting as a signal for the future path of short-term interest rates, so will be especially useful when the main policy rate is constrained by the zero lower bound. In their model, though, the risk-premium component of long-term interest rates is unaffected by any reallocation of assets between the central bank and the private sector. This is because risks are ultimately born by the private sector, even if government debt is purchased by the central bank. If the central bank makes losses on government debt then government revenue falls and taxes on the private sector have to rise to satisfy the government budget constraint.<sup>2</sup> This view is not supported by the empirical evidence in Bernanke et al. (2004), D'Amico et al. (2012), D'Amico and King (2013), Gagnon et al. (2011), Krishnamurthy and Vissing-Jorgensen (2011) and Neely (2010). Instead, these studies find strong evidence that central bank purchases of government debt have small but significant effects via the term premium component of long-term interest rates. The evidence supporting a preferred habitat mechanism comes from the "scarcity channel" in D'Amico et al. (2012) and the "safety channel" in Krishnamurthy and Vissing-Jorgensen (2011).

## 2. Model

The model economy consists of households, monopolistically competitive firms, banks, a treasury and a central bank. There is price stickiness, wages are assumed to be fully flexible, and firms use labour as the only input in the production of consumption goods.<sup>3</sup>

## 2.1. Households

The preferences of the representative household are given by

$$U_0 = E_0 \sum_{t=0}^{\infty} \beta^t \left( \chi_t^C \frac{C_t^{1-\delta}}{1-\delta} - \chi_t^L \frac{L_t^{1+\psi}}{1+\psi} \right)$$

where  $C_t \equiv [\int_0^1 C_t(i)^{(\theta_t - 1)/\theta_t} di]_{L}^{\theta_t/(\theta_t - 1)}$  is a CES consumption index composed to minimise cost and  $L_t$  is the time devoted to market employment.  $\chi_t^C$  and  $\chi_t^C$  are exogenous preference shock processes that evolve according to

$$\ln(\chi_t^C) = \rho_C \ln(\chi_{t-1}^C) + \varepsilon_t^C \quad \text{with } \varepsilon_t^C \sim N(0, \sigma_C^2)$$
(1)

$$\ln(\chi_t^L) = \rho_L \ln(\chi_{t-1}^L) + \varepsilon_t^L \quad \text{with } \varepsilon_t^L \sim N(0, \sigma_L^2)$$
<sup>(2)</sup>

The household maximises expected utility subject to the budget constraint:

$$P_t C_t + T_t + P_t^{\lambda} S_{t,t+1} = S_{t-1,t} + W_t L_t + (1 - t_\pi) (P_t Y_t - W_t L_t)$$
(3)

 $P_t \equiv [\int_0^1 P_t(i)^{1-\theta_t} di]^{1/(1-\theta_t)}$  is the price of the composite consumption good,  $T_t$  is a lump-sum tax paid to the government and  $S_{t,t+1}$  is the quantity of a savings device purchased from perfectly competitive banks at unit price  $P_t^S < 1$  in period t. The household can secure a payment of  $S_{t,t+1}$  in period t+1 by saving  $P_t^S S_{t,t+1}$  in period t.  $W_t$  is the nominal market wage. Households own firms that produce and sell consumption goods, so they receive dividend income  $(P_tY_t - W_tL_t)$  which is subject to tax at the rate  $t_{\pi}$ .<sup>4</sup> All prices are measured in units of the numeraire good "money", which is not modelled.

The first-order conditions of the household's optimisation problem are

$$1 = \beta E_t \left[ \frac{\chi_{t+1}^C}{\chi_t^C} \left( \frac{C_{t+1}}{C_t} \right)^{-\delta} \frac{1}{\Pi_{t+1}} \right] \frac{1}{P_t^S}$$

$$\tag{4}$$

<sup>&</sup>lt;sup>1</sup> See Cúrdia and Woodford (2011), Del Negro et al. (2011), Gertler and Karadi (2011), Gertler and Kiyotaki (2010), Gertler et al. (2012) and Kiyotaki and Moore (2012).

<sup>&</sup>lt;sup>2</sup> This intuition is given on page 5 of Cúrdia and Woodford (2010).

<sup>&</sup>lt;sup>3</sup> The model incorporates elements from Benigno and Woodford (2005), Gali (2008) and Woodford (2003).

<sup>&</sup>lt;sup>4</sup> The representative household views dividends as lump-sum income and does not internalise the effect of labour supply on profits.

$$\frac{W_t}{P_t} = \frac{\chi_t^L}{\chi_t^C} L_t^{\psi} C_t^{\delta}$$

with  $\Pi_{t+1} \equiv P_{t+1}/P_t$ . Eq. (4) is the intertemporal Euler equation that characterises the optimal consumption-savings decision. Eq. (5) is the intratemporal condition describing optimality between labour supply and consumption.

2.2. Firms

There is a continuum of monopolistically competitive firms indexed by  $i \in [0, 1]$ . Firm *i*'s production function is  $Y_t(i) = A_t L_t(i)^{1/\phi}$ , where  $L_t(i)$  is labour employed and  $A_t$  is an exogenous technology shock process that evolves according to

$$\ln(A_t) = \rho_A \ln(A_{t-1}) + \varepsilon_t^A \quad \text{with } |\rho_A| < 1 \quad \text{and} \ \varepsilon_t^A \sim N(0, \sigma_A^2) \tag{6}$$

As in Calvo (1983), only a fraction  $1 - \alpha$  of firms can adjust the price of their respective good in any given period. Let  $P_t^*(i)$  be the price chosen by a firm that is able to reset its price in period *t*. The evolution of the aggregate price level is then described by

$$P_t = [(1 - \alpha)P_t^*(i)^{1 - \theta_t} + \alpha P_{t-1}^{1 - \theta_t}]^{1/(1 - \theta_t)}$$

 $\theta_t$  is the time-varying elasticity of substitution between consumption goods. All firms that can change their price in period *t* choose  $P_t(i)$  to maximise the expected discounted stream of their future profits

$$E_t \sum_{T=t}^{\infty} \alpha^{T-t} M_{t,T}[P_t(i)Y_T(i) - W_T L_T(i)]$$

subject to the relevant demand constraints.

$$M_{t,T} \equiv \beta^{T-t} \frac{\chi_T^C C_T^{-\delta} P_t}{\chi_t^C C_t^{-\delta} P_T}$$

is the firm's stochastic discount factor, derived from the consumption Euler equation (4).

The first-order condition for price setting and the assumed price adjustment process imply that equilibrium inflation is given by  $^{5}$ 

$$\frac{1-\alpha\Pi_t^{\theta_t-1}}{1-\alpha} = \left(\frac{F_t}{K_t}\right)^{(\theta_t-1)/(\theta_t(\phi-1)+1)}$$
(7)

where

$$F_{t} = \chi_{t}^{C} C_{t}^{-\delta} Y_{t} + \alpha \beta E_{t} \Pi_{t+1}^{\theta_{t}-1} F_{t+1}$$
(8)

$$K_{t} = \frac{\theta_{t}\phi}{\theta_{t}-1}\chi_{t}^{L}L_{t}^{\psi}\left(\frac{Y_{t}}{A_{t}}\right)^{\phi} + \alpha\beta E_{t}\Pi_{t+1}^{\theta_{t}\phi}K_{t+1}$$

$$\tag{9}$$

 $F_t$  and  $K_t$  are auxiliary variables and

$$\ln\left(\frac{\theta_t}{\theta}\right) = \rho_\theta \ln\left(\frac{\theta_{t-1}}{\theta}\right) + \varepsilon_t^\theta \quad \text{with } \varepsilon_t^\theta \sim N(0, \sigma_\theta^2) \tag{10}$$

is the law of motion for the time-varying elasticity of substitution between consumption goods.

## 2.3. Banks

The role of the representative bank is to determine the maturity composition of the aggregate savings device offered to households. Perfect competition in the banking sector ensures that all bank revenues are returned to households, but it is the bank that decides how deposits are invested into short-term and long-term government bonds. We assume when doing so that banks perceive households as heterogeneous with regard to their desired investment horizons, an assumption consistent with the preferred habitat literature where investors value characteristics of assets other than just their payoff. In the context of our model, this means that investors are perceived as having a preference for assets with maturities that match their preferred investment horizon. Assets of other maturities are viewed as only imperfect substitutes. As a result, the price of an asset with a given maturity is influenced by supply and demand effects local to that maturity, see Vayanos and Vila (2009), and the central bank can use purchases of government bonds to influence prices and yields at different maturities.<sup>6</sup>

(5)

<sup>&</sup>lt;sup>5</sup> See Section A.1 in the appendix for the derivation.

<sup>&</sup>lt;sup>6</sup> The assumption that households are *perceived* as having heterogeneous preferences over different investment horizons is made so the model remains within a standard representative agent framework. If households differ with respect to their *actual* preferences then a full heterogeneous agent model would be needed.

Formally, in every period *t* the representative bank collects nominal deposits  $P_t^S S_{t,t+1}$  from households, which it uses to purchase  $B_{t,t+1}$  units of a short-term government bond and  $Q_{t,t+\tau}$  units of a long-term government bond. The flow budget constraint of the representative bank is

$$P_{5}^{5}S_{t,t+1} = P_{t}^{B}B_{t,t+1} + P_{\ell}^{Q}Q_{t,t+\tau}$$
(11)

A unit of the short-term bond can be purchased at price  $P_t^{\mathcal{B}}$  in *t* and has a payoff of one in the next period t+1. The long-term bond is traded at the price  $P_t^{\mathcal{Q}}$  in *t*; a unit of this bond yields a payoff of  $1/\tau$  in every period between t+1 and  $t+\tau$ .

The bank constructs the savings device S offered to households on the basis of a function V that reflects its perception of the different investment horizons preferred by heterogenous households. The allocation problem of the representative bank is

$$\max_{B_{t,t+1},Q_{t,t+\tau}} V\left(\frac{B_{t,t+1}}{P_t},\frac{Q_{t,t+\tau}}{P_t}\right)$$

subject to the flow constraint (11).<sup>7</sup> The asset demand schedules that solve the allocation problem depend on the functional form chosen for *V*. We prefer not to impose restrictive properties on the demand curves, so borrow from the empirical literature on demand estimation and adopt the flexible functional form of the Generalised Translog (GTL) model introduced by Pollak and Wales (1980). Rather than specifying *V* directly, the GTL model specifies the indirect utility function  $V^* \equiv V(B^*/P, Q^*/P)$ :

$$\log(V_{t}^{*}) = a_{0} + \sum_{k} a_{1}^{k} \log\left(\frac{P_{t}^{k}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right) + \frac{1}{2} \sum_{k} \sum_{l} a_{2}^{kl} \log\left(\frac{P_{t}^{k}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right) \log\left(\frac{P_{t}^{l}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right)$$

with  $k, l \in \{B, Q\}$ ,  $a_2^{kl} = a_2^{lk}$  and  $s_t \equiv S_{t,t+1}/P_t$ . The asset shares  $as^B \equiv P^B B/P^S S$  and  $as^Q \equiv P^Q Q/P^S S = 1 - as^B$  can be derived using the logarithmic form of Roy's identity, see Barnett and Serletis (2008) and Section A.2 in the appendix for the details.

$$as_{t}^{k} = \frac{P_{t}^{k}g^{k}}{P_{t}^{S}s_{t}} + \left(1 - \frac{P_{t}^{B}g^{B} + P_{t}^{Q}g^{Q}}{P_{t}^{S}s_{t}}\right) \frac{a_{1}^{k} + \sum_{l}a_{2}^{kl}\log\left(\frac{P_{t}^{l}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right)}{\sum_{l}a_{1}^{l} + \sum_{k}\sum_{l}a_{2}^{kl}\log\left(\frac{P_{t}^{l}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right)}$$

To ensure that the above asset shares are the result of the bank's optimisation problem, the parameter space has to be restricted such that four "integrability conditions" hold. Under these conditions, quasi-homotheticity,  $a_1 \equiv a_1^B$  and  $a_2 \equiv a_2^{BB}$ , the asset demands are

$$\frac{B_{t,t+1}}{P_t} = g^B + \frac{P_t^S s_t - P_t^B g^B - P_t^Q g^Q}{P_t^B} \left[ a_1 + a_2 \log \left( \frac{P_t^B}{P_t^Q} \right) \right]$$
(12)

$$\frac{Q_{t,t+\tau}}{P_t} = g^Q + \frac{P_t^S s_t - P_t^B g^B - P_t^Q g^Q}{P_t^Q} \left[ 1 - a_1 - a_2 \log\left(\frac{P_t^B}{P_t^Q}\right) \right]$$
(13)

The income of the representative bank from its holdings of long-term bonds in period t is

$$\frac{1}{\tau}\sum_{j=1}^{\tau}Q_{t-j,t+\tau-j}$$

Perfect competition in the banking sector requires that banks return all their revenues from government bonds to depositors, so the return to a household depositing  $P_{t-1}^{S}S_{t-1,t}$  is

$$S_{t-1,t} = B_{t-1,t} + \frac{1}{\tau} \sum_{j=1}^{\tau} Q_{t-j,t+\tau-j}$$
(14)

The prices  $P_t^B$  and  $P_t^Q$  of the short-term and long-term government bonds are known with certainty in period *t* but not in advance. The gross nominal interest rate paid on the one-period bond is

$$1 + i_t = \frac{1}{P_t^B} \tag{15}$$

<sup>&</sup>lt;sup>7</sup> The optimisation problem is equivalent to that of a bank in a model where *V* aggregates the heterogeneous preferences of households over bonds of different maturities.

For comparison purposes, it is possible to calculate an interest rate associated with the  $\tau$ -period bond traded in *t*. It is implicitly defined by

$$P_t^{Q} = \frac{\frac{1}{\tau}}{1+i_t^{Q}} + \frac{\frac{1}{\tau}}{(1+i_t^{Q})^2} + \frac{\frac{1}{\tau}}{(1+i_t^{Q})^3} + \dots + \frac{\frac{1}{\tau}}{(1+i_t^{Q})^{\tau}} = \frac{1}{\tau} \frac{1}{1+i_t^{Q}} \frac{1-\left(\frac{1}{1+i_t^{Q}}\right)^{\tau}}{1-\frac{1}{1+i_t^{Q}}}$$
(16)

where  $i_t^Q$  is the per-period interest rate that equates the unit price  $P_t^Q$  with the value of the discounted payoff stream from a unit investment in the long-term bond.

An important feature of the bank behaviour is that the closed-form asset demand schedules are simple and intuitive, in contrast with previous contributions to the literature on unconventional monetary policy. Both demand curves are downward sloping for small enough values of  $a_2$ . Low asset quantities are associated with high asset prices, which allows unconventional monetary policy instruments to work through a scarcity channel. For example, central bank purchases of long-term bonds reduce the quantity of those bonds available to the banks and thus increase their price.

#### 2.4. Government

The government's economic policy is implemented by the actions of a treasury and a central bank. We model the operations of the treasury in a simplified way to maintain the focus of our paper on monetary policy.

The treasury issues both short and long-term government debt. Short-term bonds are issued in a quantity consistent with the central bank's setting of the short-term nominal interest rate. The quantity of long-term bonds issued in period *t* is  $\overline{Q}_{t,t+\tau}$ , determined by a simple rule

$$\frac{\overline{Q}_{t,t+\tau}}{P_t} = fY \tag{17}$$

to maintain constant real issuance of long-term bonds each period. f > 0 and Y is steady-state output. Long-term bonds can only be purchased from the treasury in the period they are issued and then have to be held until maturity, i.e. we follow Sargent (1987, pp. 102–105) and Andrés et al. (2004) in assuming that there is no secondary market for long-term government debt.<sup>8</sup>

The treasury uses lump-sum taxes to finance government spending. The government consumption good  $G_t$  has the same CES aggregator as the composite household consumption good and is given exogenously by

$$\ln\left(\frac{G_t}{G}\right) = \rho_G \ln\left(\frac{G_{t-1}}{G}\right) + \varepsilon_t^G \quad \text{with } \varepsilon_t^G \sim N(0, \sigma_G^2)$$
(18)

with *G* being the steady state value of government spending on consumption goods. Lump-sum taxes satisfy  $T_t = P_t G_t$ . The central bank sets the short-term nominal interest rate according to the following rule:

$$\frac{1+i_t}{1+i} = \left(\frac{\Pi_t}{\Pi}\right)^{\gamma_{\Pi}} \left(\frac{Y_t}{Y}\right)^{\gamma_{Y}} \nu_t \tag{19}$$

Variables without time subscript denote steady-state values and  $\nu_t$  is an interest rate shock term that evolves according to

$$\ln(\nu_t) = \rho_{\nu} \ln(\nu_{t-1}) + \varepsilon_t^{\nu} \quad \text{with } \varepsilon_t^{\nu} \sim N(0, \sigma_{\nu}^2)$$
<sup>(20)</sup>

Asset purchases are carried out according to a Taylor-type rule:

$$\frac{\overline{Q}_{t,t+\tau} - Q_{t,t+\tau}^{CB}}{\overline{Q}_{t,t+\tau}} = \left(\frac{\Pi_t}{\Pi}\right)^{\gamma_{T}^{QE}} \left(\frac{Y_t}{Y}\right)^{\gamma_{Y}^{QE}} \xi_t$$
(21)

where  $Q_{t,t+\tau}^{CB}$  is the quantity of long-term bonds purchased by the central bank in period *t*.<sup>9</sup> The logarithm of the shock  $\xi_t$  follows an AR(1) process.

$$\ln(\xi_t) = \rho_{\xi} \ln(\xi_{t-1}) + \varepsilon_t^{\xi} \quad \text{with } \varepsilon_t^{\xi} \sim N(0, \sigma_{\xi}^2)$$
(22)

<sup>&</sup>lt;sup>8</sup> If there is a secondary market in long-term government debt then long-term and short-term bonds become perfect substitutes and it is difficult to maintain the assumption of a preferred habitat across the two different types of bond.

<sup>&</sup>lt;sup>9</sup> Only the net supply of long-term bonds matters in the model, so it would be possible to abstract from the supply of bonds by the treasury and work instead with an equation for the net supply of long-term bonds. The distinction is retained to avoid confusion between questions of issuance by the treasury and asset purchases by the central bank. Note that such a net bond supply rule can be obtained by combining (17) and (21). However, all fluctuations in the real supply of the long-term bond result from central bank operations.

The central bank is a net buyer of long-term bonds of the type issued in *t* if  $Q_{t,t+\tau}^{CB} > 0$  and is a net supplier of those to the market if  $Q_{t,t+\tau}^{CB} < 0.^{10}$  For example, if inflation and output are below their respective steady-state values then with  $\gamma_{II}^{QE} > 0$ ,  $\gamma_{Y}^{QE} > 0$  and  $\xi_t = \xi = 1$  the central bank stimulates the economy by purchasing long-term bonds. Conversely, if inflation and output lie above their steady-state values then asset sales are used to depress prices and productive activity.

The treasury and central bank are subject to a consolidated budget constraint that equates government revenue to government expenditures:

$$P_{t}^{B}B_{t,t+1} + P_{t}^{Q}\overline{Q}_{t,t+\tau} + T_{t} + t_{\pi}(P_{t}Y_{t} - W_{t}L_{t}) + \pi_{t}^{CB} = P_{t}G_{t} + B_{t-1,t} + \frac{1}{\tau}\sum_{j=1}^{\tau}\overline{Q}_{t-j,t+\tau-j}$$

 $\pi t_{c}^{EB}$  are central bank profits (or losses) from asset purchases. The combination of perfect competition in the banking sector and goods markets together with lump-sum funding of current government expenditure means that the model's consolidated government budget constraint is always satisfied. Section A.3 of the appendix gives full details.

#### 2.5. Market clearing

The model is completed by conditions for clearing in bond, goods and labour markets. Demand and supply in the market for long-term bonds are equated for

$$\overline{Q}_{t,t+\tau} = Q_{t,t+\tau} + Q_{t,t+\tau}^{CB}$$
(23)

The market for short-term bonds clears and the aggregate resource constraint in goods markets is

$$Y_t = C_t + G_t \tag{24}$$

Labour market clearing requires that hours supplied by the representative household  $L_t$  are equal to aggregate hours demanded by the firms,  $\int_0^1 L_t(i) di$ , implying that aggregate production is

$$Y_t = A_t \left(\frac{L_t}{D_t}\right)^{1/\phi}$$
(25)

where  $D_t \equiv \int_0^1 [P_t(i)/P_t]^{-\theta_t \phi} di$  is a measure of price dispersion. The dynamics of the price dispersion term are given by<sup>11</sup>

$$D_t = (1 - \alpha) \left(\frac{1 - \alpha \Pi_t^{\theta_t - 1}}{1 - \alpha}\right)^{\frac{\eta_t - 1}{\theta_t - 1}} + \alpha \Pi_t^{\theta_t \phi} D_{t-1}$$
(26)

Price dispersion is a source of inefficiency in the model. It acts in addition to the mark-up distortions created by the market power of firms.

#### 2.6. Model summary and calibration

Eqs. (1)–(26) are sufficient to describe the behaviour of the endogenous variables in rational expectations equilibrium. Real variables are stationary, but for  $\Pi > 1$  there is a positive trend in all nominal variables. Section B.1 of the appendix shows how we take a first-order numerical approximation of a trend-stationary version of the model and simulate it around the steady state described in Section B.2 of the appendix. In what follows we define  $s_t \equiv S_{t,t+1}/P_t$ ,  $b_t \equiv B_{t,t+1}/P_t$  and  $q_t \equiv Q_{t,t+\tau}/P_t$ .

Table 1 gives an overview of the model calibration. In what follows, the calibration of the parameters in the household and firm problems is standard and in line with Gali (2008) and Smets and Wouters (2003, 2007). The household discount factor is 0.99. The inverses of the intertemporal substitution elasticities in consumption and labour supply are 2 and 0.5 respectively. The intratemporal elasticity of substitution between consumption goods equals 6, which implies a steady-state mark-up of 20 per cent. The production function exhibits decreasing returns to scale. Price rigidity is calibrated to a relatively high value, however wages are fully flexible in the model. Steady-state inflation corresponds to an annual inflation rate of close to 2 per cent.  $\tau$  is 20 so the long-term bond has a maturity of 5 years. The government spending share of GDP is set to 40 per cent. This is at the upper end for the US and at the lower end for most European countries. Half of firm profits are paid to the households, the other half to the government, reflecting corporate taxes as well as public ownership of goods producing firms.

The calibration of the asset supply and demand equations generates a steady state in bond markets and a response to central bank asset purchases that is in line with empirical estimates. We target steady-state asset prices  $P^{B}$  and  $P^{Q}$  that translate into annualised interest rates on 1-period and 20-period bonds of 4.5 and 5.5 per cent respectively, in line with the average interest paid on 3-month and 5-year US Treasury Bills between the start of the Greenspan era in 1987 and the end of

<sup>&</sup>lt;sup>10</sup> Since long-term bonds are only traded in the period in which they are issued, unconventional policy in our model should not be viewed as changing the existing stock of long-term bonds held by the central bank. It should instead be seen as affecting the supply of an asset available for purchase at a particular point in time.

<sup>&</sup>lt;sup>11</sup> See Section A.4 in the appendix for derivations.

Table 1	
Calibration	

Parameter	Value	Description			
β	0.99	Household discount factor

2007. The only parameterisation of the issuance equation for long-term bonds that is consistent with these steady-state bond prices and parameters already calibrated is f equal to 0.66. This parameterisation means that long-term government debt accounts for an acceptable 36 per cent share of the government's total steady-state outstanding debt obligations.

A realistic response to central bank asset purchases is achieved through the calibration of the parameters  $a_1, a_2, g^B$  and  $g^Q$  in the asset demand equations. We set  $a_2 = 0$  without loss of generality because the logarithmic term in the asset demand equations is redundant when the model is solved to a first-order approximation. With this, the asset demand equation for the long-term bond can be written as

$$q_t = g^{Q} + \frac{1 - a_1}{a_1} \frac{P_t^{B}}{P_t^{Q}} (b_t - g^{B})$$

and  $g^B$  and  $g^Q$  can be interpreted as the parts of demand that do not react to relative prices, sometimes referred to as the "subsistence levels" of demand in consumer theory.  $a_1$  determines the relative marginal gain in the objective of the bank from holding the short-term rather than the long-term bond, similar to the parameter in first-order homogeneous Cobb-Douglas preferences. The values of  $a_1, g^B, g^Q$  are chosen such that the yield on the long-term bond falls by 100 basis points (bps) if the central bank makes asset purchases that reduce the present discounted value of long-term payment obligations to the private sector by 1.5 per cent. In quantitative terms, this translates to the yield on long-term debt falling by 7 bps after central bank asset purchases that remove \$100 billion of long-term payment obligations to the private sector.<sup>12</sup> This is consistent with the empirical estimates of a 3–15 bps fall in long-term yields per \$100 billion of asset purchases reported in various contributions, summarised in Table 1 of Chen et al. (2012).

The calibration of the shock processes emphasises the significance of shocks to government spending and the elasticity of substitution, creating a reasonable amount of volatility in macroeconomic aggregates. The standard deviation of nominal US GDP growth 1987:4-2007:4 was 0.022, which compares favourably to a standard deviation of 0.028 from simulations of the model. The model somewhat understates output volatility and overstates inflation volatility compared to US data. In Section 3.3, we report the contribution of each shock to total volatility in output, inflation and interest rates.

<sup>&</sup>lt;sup>12</sup> We arrive at our estimate of 7 bps as follows. Asset purchases that reduce the present discounted value of coupon payments on long-term debt payable to households in the model by 0.013 correspond to a 10 bps decrease in the annualised long-term yield. GDP in the US in 2007 was approximately \$14 trillion. In our model, steady-state GDP is 1.3 so if 0.013/1.3 corresponds to 10 bps then 100/14,000 corresponds to 7 bps.

#### 3. Conventional and unconventional monetary policy

The possibility of purchasing long-term government debt presents the central bank with an additional tool to help stabilise the economy. To understand the implications of this, it is useful to begin with a discussion of how conventional and unconventional monetary policy actions are transmitted in the model.<sup>13</sup>

#### 3.1. Transmission mechanisms

The response of the economy to an expansionary shock in the rule for the short-term nominal interest rate (19) is depicted in Fig. 1; the response to an expansionary shock in the rule for long-term bond purchases (21) is shown in Fig. 2. Both figures are obtained under the calibration  $\gamma_{II} = 1.01$ ,  $\gamma_{Y} = 0.3$  and  $\gamma_{II}^{QE} = 0$ ,  $\gamma_{Y}^{QE} = 60$  for conventional and unconventional monetary policies. A value of 60 for  $\gamma_{Y}^{QE}$  implies in steady state that a 1 per cent decrease in output leads to the central bank buying approximately 45 per cent of the new long-term bonds issued in that period. This amounts to less than 5 per cent of all outstanding long-term debt.

The shock to the interest rate rule immediately decreases the short-term nominal interest rate and equivalently increases the price of the short-term bond. Demand for the short-term bond therefore falls. The subsequent rise in  $P^{\beta}$  also increases the price of the composite savings device available to households, leading to a decrease in savings  $P^{S}s$  and a rise in both output and consumption. The rise in output is accompanied by inflation above its steady-state level. The shock has a less persistent impact on output than inflation because inflation induces relative price distortions that mitigate the rise in output.

The effects on the market for long-term bonds work through two channels. A decrease in savings shifts down the demand curve for the long-term bond, which puts downward pressure on its price  $P^Q$ . In addition, output and inflation rise above their respective steady-state levels so the central bank uses unconventional monetary policy to sell long-term government bonds. This increases the quantity of long-term bonds available to the private sector, further decreasing their price.

Prices quickly return to their steady-state values once the shock to the short-term nominal interest rate has passed. The temporary decline in the yield of the short-term bond gives rise to a rebalancing of the representative household's bond portfolio in favour of long-term debt. This causes the return from deposits *s* to decline immediately and to only gradually recover as the coupon payments from the higher level of long-term debt are collected and the share of short-term debt slowly rises again. The recovery is supported by an increase in hours worked.

Fig. 2 shows the response of the economy to an expansionary shock in the central bank's long-term bond purchase rule (21). The unanticipated rise in central bank purchases of long-term bonds  $q^{CB}$  reduces the supply of this asset to the private sector and pushes up its price. The increase in  $P^Q$  similarly increases the price of the composite savings device  $P^S$ , causing households to save less, consume more and supply more labour to firms. Output then increases and prices grow at a faster rate. The rise in the price  $P^Q$  of the long-term bond is associated with a decline in the long-term interest rate, as can be seen from Eq. (16) defining  $i^Q$ . This corresponds to a "flattening of the yield curve" effect generally attributed to purchases of long-term government securities.

The decline in savings shifts the demand curves for both types of bonds inwards, leading to a fall in the quantity of the short-term bond held by the private sector. The fall in holdings is though limited because the central bank subsequently follows its interest rate rule and increases the short-term nominal interest rate, thereby reducing the price of the short-term bond and restoring some of its demand. Savings  $P^{S}s$  only gradually return to their steady-state level after the unexpected purchases of long-term bonds. Labour supply similarly remains elevated for a number of periods, which helps bring savings back to their steady-state level and ameliorates the negative output effects that inflation causes through price dispersion.

The impulse response functions suggest that both conventional and unconventional monetary policies may be effective at stabilising the economy. In what follows, the focus is on the benefits of allowing the central bank to purchase long-run government bonds as an unconventional policy that acts as a supplement to conventional short-term interest rate policy.

#### 3.2. Optimised policy rules

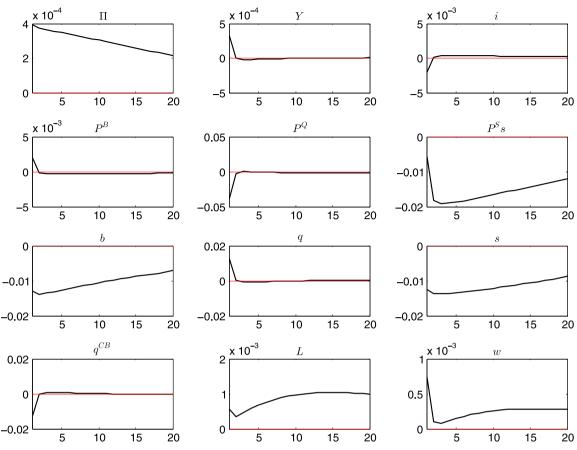

Let the central bank loss function be

$$\Omega = \omega_{\Pi} \operatorname{Var}(\Pi_t - \Pi) + \omega_Y \operatorname{Var}(Y_t - Y) + \omega_i \operatorname{Var}(i_t - i) + \omega_0 \operatorname{Var}(i_t^Q - i^Q)$$

where  $\omega_{II}$ ,  $\omega_Y$ ,  $\omega_i$  and  $\omega_Q$  are positive weights. Losses are therefore a weighted sum of the variances of inflation, output and interest rates.<sup>14</sup> This specification allows for the volatility of both short-term and long-term interest rates to enter the central bank's considerations, although in the baseline case we set  $\omega_i$  and  $\omega_0$  to zero.

<sup>&</sup>lt;sup>13</sup> A full set of impulse response functions is available from the authors on request.

<sup>&</sup>lt;sup>14</sup> Woodford (2003) shows that, in the presence of transactions frictions, a welfare-theoretic loss function derived from a second-order approximation to household utility contains an interest-rate-volatility term.

The central bank sets the interest rate rule parameters  $\gamma_{II}$  and  $\gamma_{Y}$  together with the asset purchase rule parameters  $\gamma_{II}^{QE}$ and  $\gamma_{Y}^{QE}$ , subject to the constraints imposed by the model and assumed feasibility constraints  $\gamma_{II} \in [1, 6]$ ,  $\gamma_{Y} \in [0, 6]$  and  $\gamma_{II}^{QE}$ ,  $\gamma_{Y}^{QE} \in [0, 75]$ . We allow for a high upper bound on the set of feasible interest rate rule parameters so that the benefits of unconventional monetary model do not arise solely when the feasibility constraints for  $\gamma_{II}$  and  $\gamma_{Y}$  are binding. A lower upper bound on the set of interest rate rule parameters would likely make unconventional policy even more effective, as the central bank would then find it more difficult to stabilise the economy through conventional policy.

Table 2 shows optimised policy rules for different weights on inflation and output stabilisation in the central bank's loss function, with  $\omega_i$  and  $\omega_Q$  set to zero so the central bank is not concerned about stabilising interest rates. For each set of weights, the first row presents results when the central bank uses only conventional monetary policy. In this baseline case, coefficients on the asset purchase rule are set to zero and only the coefficients on the interest rate rule are optimised. For the next case, the central bank fixes the coefficients of the interest rate rule at their baseline values, but optimises over the coefficients in the asset purchase rule. This experiment shows the improvements attainable if the central bank starts purchasing long-term government bonds without internalising the potential effect this has on optimal interest rate policy. In the final case, the central bank acknowledges the complementarity of conventional and unconventional policies by jointly optimising over the parameters in the interest rate and asset purchase rules.

The benefits of unconventional monetary policy are small if the central bank's interest rate rule is not adjusted to account for purchases of long-term government bonds. However, when both policies are jointly optimised then the ability of the central bank to stabilise inflation and output is greatly improved. The use of unconventional monetary policy reduces losses by more than 17 per cent compared to the baseline case, provided conventional monetary policy is adjusted accordingly. The optimal policy mix is dichotomised, assigning conventional short-term interest rate policy to react to inflation and unconventional asset purchasing policy to react to output. An important prerequisite for this result is that conventional and unconventional policies differ in their impact on inflation and output, so interventions on one margin are not exactly offset at another margin.

The final column of Table 2 provides an interpretation of welfare losses in terms of an equivalent change in annualised steady-state inflation, using a metric due to Jensen (2002). For example, comparing the losses in the third row to those in the first row shows that not allowing the central bank to make asset purchases causes welfare losses equivalent to a rise in steady-state inflation of 1.64 percentage points. The derivation of the equivalent steady-state inflation measure is explained in Section A.5 of the appendix.

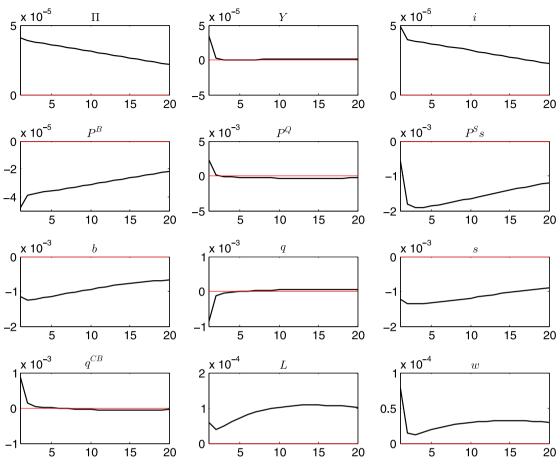

Fig. 2. Response to an expansionary shock to purchases of the long-term bond.

(f): fixed, i.e. not chosen optimally.

Table 3 suggests that unconventional monetary policy is more effective when the central bank is also concerned about the volatility of interest rates. If only variability in the short-term interest rate is costly then the unconventional policy of purchasing long-term government bonds almost completely replaces conventional short-term interest rate policy. The optimal interest rate rule parameters are at the respective lower bounds of the feasibility sets. Large gains arise because long-term interest rate volatility from asset purchases is costless and substituting conventional policy with asset purchases avoids the losses that arise from movements in the short-term interest rate. The final part of the table shows that the gains from the unconventional tool are still significant when there is a positive weight on the variance of the long-term interest rate in the loss function. These gains are slightly smaller than in the previous case, but still larger than in Table 2 when the central bank is not concerned with interest rate volatility.

#### 3.3. Loss decomposition

To show the effect of the different policy regimes on the losses due to each type of shock, we focus on the case where the weights in the loss function are given by  $(\omega_{\Pi}, \omega_{Y}, \omega_{i}, \omega_{Q}) = (80, 20, 0, 0)$ . In Table 4 the variances of all but one shock are set to zero. The shock of interest is indicated in the first column and has its variance calibrated as in Table 1. Policy parameters, when not set to zero, take the value that is optimal when all shocks are operating jointly.

A large proportion of the overall welfare gains arise because combining conventional and unconventional policy is particularly effective at stabilising the effects of shocks to government spending and the elasticity of substitution. Table 1 shows these shocks make a significant contribution to volatility in the model. Unconventional policy has smaller but noticeable effects on volatility due to shocks to the interest rate rule, consumption preferences and productivity. It does not perform significantly better in the face of labour supply and bond purchase shocks. In general, the volatility of both output and inflation falls when unconventional policy is introduced alongside conventional policy. The exception is if there are only shocks to the interest rate rule and technology, in which case the fall in inflation volatility comes at the cost of a small rise in the volatility of output.

The benefits from unconventional policy can be seen in Fig. 3, which compares the impulse responses of a shock to the elasticity of substitution under the baseline policy (dashed line) and the optimal combined conventional and unconventional policy (solid line). Inflation reacts less to the shock when the central bank purchases government bonds. Output initially reacts more, but overall is less volatile.

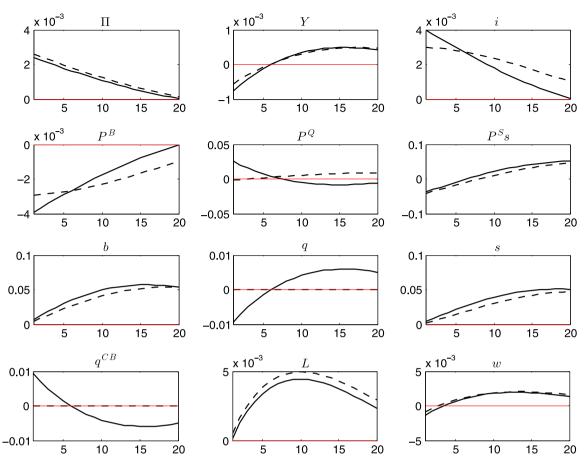

Fig. 3. Response to a shock to the elasticity of substitution for short-term interest policy only (dashed) and with conventional and unconventional policy (solid).

## 4. Conclusion

Our results call for central banks to consider purchasing long-term government bonds, even when the economy is not in financial crisis. Unconventional asset purchases of this type are a valuable addition to the tool kit of a central bank trying to stabilise inflation and output, whatever the state of the economy and not just when the short-term nominal interest rate is constrained by the zero lower bound. In order to reap the full benefit, though, it is important to coordinate unconventional and conventional monetary policy. In our model, this means that the short-term interest rate should respond to inflation while the central bank's purchases of long-term debt should respond to output. Unconventional monetary policy plays an even more important role if the central bank is additionally concerned about interest rate volatility. The 'Maturity Extension Program and Reinvestment Policy" announced by the Federal Reserve in September 2011 is an example of the type of unconventional monetary policy measure we advocate.<sup>15</sup> Under this programme, the Federal Reserve lengthens the average maturity of its government bond portfolio by selling short-term treasuries and re-investing the proceeds in long-term treasuries. Our results suggest that such operations may become increasingly important even when financial crisis has passed.

The benefit of unconventional monetary policy in our model is indicative of more general gains available from the coordination of monetary policy and the debt management of fiscal authorities. In our model, central bank purchases of long-term government bonds are equivalent to a reduced issuance of these bonds by the fiscal authority. Whilst our results abstract from active debt management by the treasury, Borio and Disyatat (2010) argue that fiscal authorities may be tempted to reduce debt financing costs by increasing the maturity of new debt at a time when long-term interest rates are relatively low. This is problematic, because it implies that any attempt by the central bank to use unconventional asset purchases to stimulate the economy may be unwound by the treasury issuing more long-term government debt.

<sup>&</sup>lt;sup>15</sup> In reference to a comparable programme from the 1960s, this policy is sometimes referred to as "Operation Twist" or "Operation Twist Again."

#### **Appendix A. Derivations**

A.1. Firms

The profit maximisation problem of a firm i that can adjust its price in period t is

$$\max_{P_t(i)} E_t \sum_{T=t}^{\infty} \alpha^{T-t} M_{t,T}[P_t(i)Y_T(i) - W_T L_T(i)]$$
(A.1)

subject to

$$Y_T(i) = Y_T \left[ \frac{P_t(i)}{P_T} \right]^{-\theta_t}$$
(A.2)

Eq. (A.2) is the aggregate demand for firm *i*'s product.<sup>16</sup> Firm *i*'s production function implies that  $L_T(i) = [Y_T(i)/A_T]^{\phi}$  which, together with (A.2), can be used to rewrite *i*'s optimisation problem as

$$\max_{P_t(i)} E_t \sum_{T=t}^{\infty} \alpha^{T-t} M_{t,T} \left\{ P_t(i) Y_T \left[ \frac{P_t(i)}{P_T} \right]^{-\theta_t} - W_T \left( \frac{Y_T}{A_T} \right)^{\phi} \left[ \frac{P_t(i)}{P_T} \right]^{-\theta_t \phi} \right\}$$
(A.3)

The first-order condition is

$$E_t \sum_{T=t}^{\infty} \alpha^{T-t} M_{t,T} \left\{ Y_T \left[ \frac{P_t^*(i)}{P_T} \right]^{-\theta_t} - \theta_t Y_T \left[ \frac{P_t^*(i)}{P_T} \right]^{-\theta_t} + \theta_t \phi \frac{W_T}{P_T} \left( \frac{Y_T}{P_T} \right)^{\phi} \left[ \frac{P_t^*(i)}{P_T} \right]^{-\theta_t \phi - 1} \right\} = 0$$
(A.4)

By substituting in for the real wage from (5), and using the definition of the stochastic discount factor, the first-order condition can be expressed as

$$E_{t}\sum_{T=t}^{\infty} (\alpha\beta)^{T-t} \chi_{T}^{C} C_{T}^{-\delta} Y_{T} \left(\frac{P_{T}}{P_{t}}\right)^{\theta_{t}-1} = \left[\frac{P_{t}}{P_{t}^{*}(i)}\right]^{\theta_{t}\phi+1-\theta_{t}} E_{t}\sum_{T=t}^{\infty} (\alpha\beta)^{T-t} \frac{\theta_{t}\phi}{\theta_{t}-1} \chi_{T}^{L} L_{T}^{\psi} \left(\frac{Y_{T}}{A_{T}}\right)^{\phi} \left(\frac{P_{T}}{P_{t}}\right)^{\theta_{t}\phi}$$
(A.5)

Defining

$$F_t \equiv E_t \sum_{T=t}^{\infty} \left(\alpha\beta\right)^{T-t} \chi_T^C C_T^{-\delta} Y_T \left(\frac{P_T}{P_t}\right)^{\theta_t - 1}$$
(A.6)

$$K_t \equiv E_t \sum_{T=t}^{\infty} (\alpha \beta)^{T-t} \frac{\theta_t \phi}{\theta_t - 1} \chi_T^L U_T^{\psi} \left(\frac{Y_T}{A_T}\right)^{\phi} \left(\frac{P_T}{P_t}\right)^{\theta_t \phi}$$
(A.7)

followed by rearranging yields

$$\frac{P_t^*(i)}{P_t} = \left(\frac{K_t}{F_t}\right)^{1/(\theta_t(\phi-1)+1)}$$
(A.8)

Benigno and Woodford (2005) show in an analogous problem that (A.8) is both necessary and sufficient for an optimum. Note that  $F_t$  and  $K_t$  can be written recursively:

$$F_t = \chi_t^C C_t^{-\delta} Y_t + \alpha \beta E_t \Pi_{t+1}^{\theta_t - 1} F_{t+1}$$
(A.9)

$$K_t = \frac{\theta_t \phi}{\theta_t - 1} \chi_t^L L_t^{\psi} \left( \frac{Y_t}{A_t} \right)^{\phi} + \alpha \beta E_t \Pi_{t+1}^{\theta_t \phi} K_{t+1}$$
(A.10)

The above equations are those shown in the paper.

The price level in the economy is

$$P_t = [(1-\alpha)P_t^*(i)^{1-\theta_t} + \alpha P_{t-1}^{1-\theta_t}]^{1/(1-\theta_t)}$$
(A.11)

<sup>&</sup>lt;sup>16</sup> This demand schedule is standard in models with monopolistically competitive producers, see Woodford (2003) for a derivation.

Rearranging vields

$$\frac{P_t^*(i)}{P_t} = \left(\frac{1 - \alpha \Pi_t^{\theta_t - 1}}{1 - \alpha}\right)^{1/(1 - \theta_t)} \tag{A.12}$$

Combining the above equation with (A.8) gives

$$\frac{1 - \alpha \Pi_t^{\theta_t - 1}}{1 - \alpha} = \left(\frac{F_t}{K_t}\right)^{\theta_t - 1/(\theta_t(\phi - 1) + 1)}$$
(A.13)

which is the same as Eq. (7) in Section 2.2.

#### A.2. Asset demand equations

In the GTL model, the asset shares  $as^B \equiv P^B B / P^S S$  and  $as^Q \equiv P^Q Q / P^S S = 1 - as^B$  are

$$as_{t}^{k} = \frac{P_{t}^{k}g^{k}}{P_{t}^{S}s_{t}} + \left(1 - \frac{P_{t}^{B}g^{B} + P_{t}^{Q}g^{Q}}{P_{t}^{S}s_{t}}\right) \frac{a_{1}^{k} + \sum_{l}a_{2}^{kl}\log\left(\frac{P_{t}^{l}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right)}{\sum_{l}a_{1}^{l} + \sum_{k}\sum_{l}a_{2}^{kl}\log\left(\frac{P_{t}^{l}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right)$$
(A.14)

where  $k, l \in \{B, Q\}$  and symmetry requires that  $a_2^{kl} = a_2^{lk}$ . Demand curves are quasi-homothetic if they have linear Engel curves, i.e. the demand for an asset increases linearly with income. We impose quasi-homotheticity to limit wealth effects, which implies that  $a_2^{BB} + a_2^{QB} = 0$  and  $a_2^{BQ} + a_2^{QQ} = 0$ . Together with symmetry this implies that  $a_2^{BB} = a_2^{QQ} = -a_2^{QB}$ . Making the common normalisation  $a_1^B + a_1^Q = 1$  and defining  $a_1 \equiv a_1^B$  and  $a_2 \equiv a_2^{BB}$ , the asset shares are

$$as_{t}^{B} = \frac{P_{t}^{B}g^{B}}{P_{t}^{S}s_{t}} + \left(1 - \frac{P_{t}^{B}g^{B} + P_{t}^{Q}g^{Q}}{P_{t}^{S}s_{t}}\right) \times \left[a_{1} + a_{2}\log\left(\frac{P_{t}^{B}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right) - a_{2}\log\left(\frac{P_{t}^{Q}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right)\right]$$
(A.15)

$$as_{t}^{Q} = \frac{P_{t}^{Q}g^{Q}}{P_{t}^{S}s_{t}} + \left(1 - \frac{P_{t}^{B}g^{B} + P_{t}^{Q}g^{Q}}{P_{t}^{S}s_{t}}\right) \times \left[1 - a_{1} - a_{2}\log\left(\frac{P_{t}^{B}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right) + a_{2}\log\left(\frac{P_{t}^{Q}}{P_{t}^{S}s_{t} - P_{t}^{B}g^{B} - P_{t}^{Q}g^{Q}}\right)\right]$$
(A.16)

which after rearranging is

$$\frac{B_{t,t+1}}{P_t} = g^B + \frac{P_t^S s_t - P_t^B g^B - P_t^Q g^Q}{P_t^B} \left[ a_1 + a_2 \log\left(\frac{P_t^B}{P_t^Q}\right) \right]$$
(A.17)

$$\frac{Q_{t,t+\tau}}{P_t} = g^Q + \frac{P_t^S s_t - P_t^B g^B - P_t^Q g^Q}{P_t^Q} \left[ 1 - a_1 - a_2 \log\left(\frac{P_t^B}{P_t^Q}\right) \right]$$
(A.18)

Marshallian demands satisfy (i) positivity, (ii) adding up, (iii) homogeneity of degree zero in prices and income and (iv) symmetry and negative semi-definiteness of the matrix of substitution effects. Thus, the above demand system is only consistent with the firm's maximisation problem stated in Section 2.3 if it satisfies these four "integrability conditions" (Barnett and Serletis, 2008). (A.17) and (A.18) satisfy (ii) and (iii), (i) will be satisfied by an adequate calibration and (iv) remains to be checked post simulation.

## A.3. Government budget constraint

The budget constraint of the representative household is given by

$$P_t C_t + T_t + P_t^S S_{t,t+1} = S_{t-1,t} + W_t L_t + (1 - t_\pi) (P_t Y_t - W_t L_t)$$
(A.19)

Additionally, we have

$$Y_t = C_t + G_t \tag{A.20}$$

$$P_t^{S}S_{t,t+1} = P_t^{B}B_{t,t+1} + P_t^{Q}Q_{t,t+\tau}$$
(A.21)

$$S_{t-1,t} = B_{t-1,t} + \frac{1}{\tau} \sum_{j=1}^{\tau} Q_{t-j,t+\tau-j}$$
(A.22)

$$\overline{Q}_{t,t+\tau} = Q_{t,t+\tau} + Q_{t,t+\tau}^{CB}$$
(A.23)

Central bank profits from asset purchases are given by

$$\pi_t^{CB} = \frac{1}{\tau} \sum_{j=1}^{\tau} Q_{t-j,t+\tau-j}^{CB} - P_t^Q Q_{t,t+\tau}^{CB}$$
(A.24)

and firm profits are equal to  $\int_0^1 [P_t(i)Y_t(i) - W_tL_t(i)] = P_tY_t - W_tL_t$ . Using the relationships listed above, the household budget constraint can be re-written as follows:

$$P_t C_t + T_t + P_t^S S_{t,t+1} = S_{t-1,t} + W_t L_t + (1 - t_\pi)(P_t Y_t - W_t L_t)$$
(A.25)

$$P_t C_t + T_t + P_t^B B_{t,t+1} + P_t^Q Q_{t,t+\tau} + t_\pi (P_t Y_t - W_t L_t) = B_{t-1,t} + \frac{1}{\tau} \sum_{j=1}^{\tau} Q_{t-j,t+\tau-j} + P_t Y_t$$
(A.26)

$$T_{t} + P_{t}^{B}B_{t,t+1} + P_{t}^{Q}\left(\overline{Q}_{t,t+\tau} - Q_{t,t+\tau}^{CB}\right) + t_{\pi}(P_{t}Y_{t} - W_{t}L_{t}) = B_{t-1,t} + \frac{1}{\tau}\sum_{j=1}^{\tau} \left(\overline{Q}_{t-j,t+\tau-j} - Q_{t-j,t+\tau-j}^{CB}\right) + P_{t}G_{t}$$
(A.27)

$$T_{t} + P_{t}^{B}B_{t,t+1} + P_{t}^{Q}\overline{Q}_{t,t+\tau} + t_{\pi}(P_{t}Y_{t} - W_{t}L_{t}) + \pi_{t}^{CB} = B_{t-1,t} + \frac{1}{\tau}\sum_{j=1}^{\tau}\overline{Q}_{t-j,t+\tau-j} + P_{t}G_{t}$$
(A.28)

This is the government budget constraint, Eq. (23).

## A.4. Price dispersion

The labour market clearing condition is

$$L_t = \int_0^1 L_t(i) \, di \tag{A.29}$$

or, using the production function of firm *i* 

$$L_t = \int_0^1 \left[ \frac{Y_t(i)}{A_t} \right]^{\phi} di$$
(A.30)

Together with (A.2) this implies

$$L_t = \int_0^1 \left\{ \frac{Y_t}{A_t} \left[ \frac{P_t(i)}{P_t} \right]^{-\theta_t} \right\}^{\phi} di = \left( \frac{Y_t}{A_t} \right)^{\phi} \int_0^1 \left[ \frac{P_t(i)}{P_t} \right]^{-\theta_t \phi} di$$
(A.31)

Defining  $D_t \equiv \int_0^1 [P_t(i)/P_t]^{-\theta_t \phi} di$  and rearranging yields

$$Y_t = A_t \left(\frac{L_t}{D_t}\right)^{1/\phi} \tag{A.32}$$

The law of motion of price dispersion (26) is derived as follows. Since only a share  $1 - \alpha$  of firms adjusts their price in every period, the dispersion of prices in *t* can be written

$$\int_{0}^{1} \left[\frac{P_{t}(i)}{P_{t}}\right]^{-\theta_{t}\phi} di = (1-\alpha) \left[\frac{P_{t}^{*}(i)}{P_{t}}\right]^{-\theta_{t}\phi} + \alpha \int_{0}^{\alpha} \left[\frac{P_{t-1}(i)}{P_{t}}\right]^{-\theta_{t}\phi} di$$
(A.33)

where without loss of generality it is assumed that the firms that are not able to reset their price in t are those indexed by  $i \in [0, \alpha]$ . After simple manipulations one obtains

$$\int_{0}^{1} \left[\frac{P_{t}(i)}{P_{t}}\right]^{-\theta_{t}\phi} di = (1-\alpha) \left[\frac{P_{t}^{*}(i)}{P_{t}}\right]^{-\theta_{t}\phi} + \alpha \Pi_{t}^{\theta_{t}\phi} \int_{0}^{\alpha} \left[\frac{P_{t-1}(i)}{P_{t-1}}\right]^{-\theta_{t}\phi} di$$
(A.34)

Since the distribution of prices among the firms that are unable to change their price in t-1 is the same as the distribution of all prices in t-1, the above equation becomes

$$\int_{0}^{1} \left[ \frac{P_{t}(i)}{P_{t}} \right]^{-\theta_{t}\phi} di = (1-\alpha) \left[ \frac{P_{t}^{*}(i)}{P_{t}} \right]^{-\theta_{t}\phi} + \alpha \Pi_{t}^{\theta_{t}\phi} \int_{0}^{1} \left[ \frac{P_{t-1}(i)}{P_{t-1}} \right]^{-\theta_{t}\phi} di$$
(A.35)

and adequate substitutions yield the final result

$$D_t = (1 - \alpha) \left( \frac{1 - \alpha \Pi_t^{\theta_t - 1}}{1 - \alpha} \right)^{\theta_t \phi / (\theta_t - 1)} + \alpha \Pi_t^{\theta_t \phi} D_{t-1}$$
(A.36)

A.5. Loss conversion

We define the loss from the "baseline" policy as

$$\Omega^{b} = \omega_{\Pi} \operatorname{Var}(\Pi_{t}^{b} - \Pi^{b}) + \omega_{Y} \operatorname{Var}(Y_{t}^{b} - Y^{b}) + \omega_{i} \operatorname{Var}(i_{t}^{b} - i^{b}) + \omega_{Q} \operatorname{Var}(i_{t}^{Q,b} - i^{Q,b})$$
(A.37)

and similarly the loss from an alternative policy that we would like to compare with the baseline policy as

$$\Omega^a = \omega_{\Pi} \operatorname{Var}(\Pi^a_t - \Pi^a) + \omega_Y \operatorname{Var}(Y^a_t - Y^a) + \omega_i \operatorname{Var}(i^a_t - i^a) + \omega_Q \operatorname{Var}(i^{Q,a}_t - i^{Q,a})$$
(A.38)

$$=\omega_{\Pi} E(\Pi_{t}^{a} - \Pi^{a})^{2} + \omega_{Y} \operatorname{Var}(Y_{t}^{a} - Y^{a}) + \omega_{i} \operatorname{Var}(i_{t}^{a} - i^{a}) + \omega_{Q} \operatorname{Var}(i_{t}^{Q,a} - i^{Q,a})$$
(A.39)

The equivalent change in steady state inflation  $\Delta \pi^*$  is then implicitly defined as

$$\omega_{\Pi} \operatorname{E}[\Pi_{t}^{a} + \Delta \pi^{*} - \Pi^{a}]^{2} + \omega_{Y} \operatorname{Var}(Y_{t}^{a} - Y^{a}) + \omega_{i} \operatorname{Var}(i_{t}^{a} - i^{a}) + \omega_{Q} \operatorname{Var}(i_{t}^{Q,a} - i^{Q,a}) = \Omega^{b}$$
(A.40)

the constant additional amount of inflation that would raise the loss from the alternative policy to the level of the baseline policy. Solving for  $\Delta \pi^*$  gives

$$\omega_{\Pi}[E(\Pi_{t}^{a} - \Pi^{a})^{2} + (\Delta\pi^{*})^{2}] + \omega_{Y} \operatorname{Var}(Y_{t}^{a} - Y^{a}) + \omega_{i} \operatorname{Var}(i_{t}^{a} - i^{a}) + \omega_{Q} \operatorname{Var}(i_{t}^{Q,a} - i^{Q,a}) = \Omega^{b}$$
(A.41)

$$\Omega^a + \omega_{\Pi} (\Delta \pi^*)^2 = \Omega^b \tag{A.42}$$

$$\Delta \pi^* = \sqrt{\frac{\Omega^b - \Omega^a}{\omega^{II}}} \tag{A.43}$$

which when annualised is the measure used in the text.

## Appendix B. Model summary

## B.1. Stationary model

Definitions:  $w_t \equiv W_t/P_t$ ,  $s_t \equiv S_{t,t+1}/P_t$ ,  $b_t \equiv B_{t,t+1}/P_t$ ,  $q_t \equiv Q_{t,t+\tau}/P_t$ ,  $\overline{q}_t \equiv \overline{Q}_{t,t+\tau}/P_t$ ,  $q_t^{CB} \equiv Q_{t,t+\tau}^{CB}/P_t$  $C = P_t^{S} + C = \frac{S_{t-1}}{2} + t_{t-1}W_t + (1 - t_{t-1})W_t$ (B.1)

$$C_t + P_t S_t + G_t = \frac{1}{\Pi_t} + \ell_{\mathcal{P}} W_t L_t + (1 - \ell_{\mathcal{P}}) Y_t$$
(B.1)

$$1 = \beta E_t \left[ \frac{\chi_{t+1}^C}{\chi_t^C} \left( \frac{C_{t+1}}{C_t} \right)^{-\delta} \frac{1}{\Pi_{t+1}} \right] \frac{1}{P_t^S}$$
(B.2)

$$w_t = \frac{\chi_t^L}{\chi_t^C} L_t^{\psi} C_t^{\delta}$$
(B.3)

$$\frac{1 - \alpha \Pi_t^{\theta_t - 1}}{1 - \alpha} = \left(\frac{F_t}{K_t}\right)^{\theta_t - 1/(\theta_t(\phi - 1) + 1)}$$
(B.4)

$$F_t = \chi_t^C C_t^{-\delta} Y_t + \alpha \beta E_t \Pi_{t+1}^{\theta_t - 1} F_{t+1}$$
(B.5)

$$K_t = \frac{\theta_t \phi}{\theta_t - 1} \chi_t^L L_t^{\psi} \left( \frac{Y_t}{A_t} \right)^{\phi} + \alpha \beta E_t \Pi_{t+1}^{\theta_t \phi} K_{t+1}$$

$$s_t = b_t + \frac{1}{\tau} \left( q_t + \sum_{k=1}^{\tau-1} \frac{q_{t-k}}{\prod_{j=0}^{k-1} \Pi_{t-j}} \right)$$
(B.7)

$$1 + i_t = \frac{1}{P_t^B} \tag{B.8}$$

$$P_t^{\rm Q} = \frac{1}{\tau} \frac{1}{1+i_t^{\rm Q}} \frac{1 - \left(\frac{1}{1+i_t^{\rm Q}}\right)^{\rm r}}{1 - \frac{1}{1+i_t^{\rm Q}}}$$
(B.9)

$$b_{t} = g^{B} + \frac{P_{t}^{S} s_{t} - P_{t}^{B} g^{B} - P_{t}^{Q} g^{Q}}{P_{t}^{B}} \left[ a_{1} + a_{2} \log \left( \frac{P_{t}^{B}}{P_{t}^{Q}} \right) \right]$$
(B.10)

$$q_{t} = g^{Q} + \frac{P_{t}^{S} s_{t} - P_{t}^{B} g^{B} - P_{t}^{Q} g^{Q}}{P_{t}^{Q}} \left[ 1 - a_{1} - a_{2} \log \left( \frac{P_{t}^{B}}{P_{t}^{Q}} \right) \right]$$
(B.11)

$$\overline{q}_t = fY \tag{B.12}$$

$$\frac{1+i_t}{1+i} = \left(\frac{\Pi_t}{\Pi}\right)^{\gamma_n} \left(\frac{Y_t}{Y}\right)^{\gamma_Y} \nu_t \tag{B.13}$$

$$\frac{\overline{q}_t - q_t^{CB}}{\overline{q}_t} = \left(\frac{\Pi_t}{\Pi}\right)^{\gamma_{\Pi}^{QE}} \left(\frac{Y_t}{Y}\right)^{\gamma_{V}^{QE}} \xi_t$$
(B.14)

$$\overline{q}_t = q_t + q_t^{CB} \tag{B.15}$$

$$Y_t = C_t + G_t \tag{B.16}$$

$$Y_t = A_t \left(\frac{L_t}{D_t}\right)^{\frac{1}{\phi}}$$
(B.17)

$$D_t = (1 - \alpha) \left(\frac{1 - \alpha \Pi_t^{\theta_t - 1}}{1 - \alpha}\right)^{\theta_t \phi / (\theta_t - 1)} + \alpha \Pi_t^{\theta_t \phi} D_{t-1}$$
(B.18)

$$\ln(\chi_t^C) = \rho_C \ln(\chi_{t-1}^C) + \varepsilon_t^C \tag{B.19}$$

$$\ln(\chi_t^L) = \rho_L \ln(\chi_{t-1}^L) + \varepsilon_t^L \tag{B.20}$$

$$\ln(A_t) = \rho_A \ln(A_{t-1}) + \varepsilon_t^A \tag{B.21}$$

$$\ln\left(\frac{\theta_t}{\theta}\right) = \rho_\theta \ln\left(\frac{\theta_{t-1}}{\theta}\right) + \varepsilon_t^\theta \tag{B.22}$$

$$\ln\left(\frac{G_t}{G}\right) = \rho_G \ln\left(\frac{G_{t-1}}{G}\right) + \varepsilon_t^G \tag{B.23}$$

$$\ln(\nu_t) = \rho_{\nu} \ln(\nu_{t-1}) + \varepsilon_t^{\nu}$$
(B.24)

$$\ln(\xi_t) = \rho_{\xi} \ln(\xi_{t-1}) + \varepsilon_t^{\xi} \tag{B.25}$$

## B.2. Steady state

This section describes the steady state of the stationary model summarised in B.1.

$$A = \chi^{C} = \chi^{L} = \nu = \xi = 1 \tag{B.26}$$

$$D = \frac{1 - \alpha}{1 - \alpha \Pi^{\theta \phi}} \left( \frac{1 - \alpha \Pi^{\theta - 1}}{1 - \alpha} \right)^{\theta \phi/(\theta - 1)} \tag{B.27}$$

$$Y = \left[\frac{1 - \alpha\beta\Pi^{\theta-1} \ \theta\phi}{1 - \alpha\beta\Pi^{\theta\phi} \ \theta-1} D^{\psi} (1 - \overline{g})^{\delta} \left(\frac{1 - \alpha\Pi^{\theta-1}}{1 - \alpha}\right)^{(\theta(\phi-1)+1)/(\theta-1)}\right]^{1/(1 - \delta - \phi(\psi+1))}$$
(B.28)

$$G = \overline{g}Y \tag{B.29}$$

$$C = Y - G \tag{B.30}$$

$$F = \frac{YC^{-\delta}}{1 - \alpha\beta\Pi^{\theta - 1}} \tag{B.31}$$

$$K = \frac{1}{1 - \alpha \beta \Pi^{\theta \phi}} \frac{\theta \phi}{\theta - 1} D^{\psi} Y^{\phi(\psi + 1)}$$
(B.32)

$$L = DY^{\phi} \tag{B.33}$$

$$w = L^{\psi} C^{\delta}$$
(B.34)

$$P^{S} = \frac{\nu}{\Pi} \tag{B.35}$$

$$q^{CB} = 0 \tag{B.36}$$

$$\overline{q} = fY \tag{B.37}$$

$$q = \overline{q} \tag{B.38}$$

$$s = \frac{H}{1 - \beta} [C + G - t_{\mathcal{P}} w L - (1 - t_{\mathcal{P}}) Y]$$
(B.39)

$$b = s - \frac{q}{\tau} \left( 1 - \frac{1}{\Pi^{\tau}} \right) \frac{\Pi}{\Pi - 1}$$
(B.40)

The asset demand equations (B.41) and (B.42) jointly determine  $P^{B}$  and  $P^{Q}$ 

$$b = g^{B} + \frac{P^{S}s - P^{B}g^{B} - P^{Q}g^{Q}}{P^{B}} \left[ a_{1} + a_{2} \log\left(\frac{P^{B}}{P^{Q}}\right) \right]$$
(B.41)

$$q = g^{Q} + \frac{P^{S}s - P^{B}g^{B} - P^{Q}g^{Q}}{P^{Q}} \left[ 1 - a_{1} - a_{2}\log\left(\frac{P^{B}}{P^{Q}}\right) \right]$$
(B.42)

Finally,

$$i = \frac{1}{p^B} - 1 \tag{B.43}$$

and  $i^{Q}$  is given implicitly by

$$P^{Q} = \frac{1}{\tau 1 + i^{Q}} \frac{1 - \left(\frac{1}{1 + i^{Q}}\right)^{\tau}}{1 - \frac{1}{1 + i^{Q}}}$$
(B.44)
