### Context

The following project is focused on the CAMP (Central Atlantic Magmatic Province), in Central Atlas, Morocco. This research project is a collaborative work with Prof E. Font (Lisbon University). It consists of a multidisciplinary project combining a geochemical, sedimentological and biostratigraphical approach which will focus on Trias-Jurassic mass extinction and particularly on the sediments deposited between the lava flows in Morocco, considered as the main trigger of this extinction event.

### Objectives and Methods

The master student will conduct a detailed study of the intertrappean sediments with the main objectives to: (1) Evaluate the depositional environment of the intertrappean sediments based on sedimentology, mineralogy, geochemistry, microfacies and microfaunas (2) Determine climatic and environmental conditions based on clay mineralogy and stable isotopes. (3) Evaluate the stratigraphy and age control based on (i) a review the paleomagnetic signals and volcanic chemostratigraphy sequence in the area of planned sections, which permit placement of the T-J boundary in the sequences and its correlation to the global marine biostratigraphic record. In the different studied sections, the sediments located under and between the trapps will be compared also to determine the paleoenvironmental changes induced by the CAMP activity.
