**Pathological development in response to environmental stress in some latest Permian foraminifers: preliminary report**

This paper presents some morphological variations observed in benthic foraminifers, particularly within the Permian biserialamminid family, that are thought to be a response to an increase in environmental stress when compared to observations in extant benthic foraminifers. The development of aberrant forms is observed below the Permian-Triassic Boundary (PTB), confirming that the well-documented biological crisis at the PTB at the end of the Permian is gradual
